

ASSESSMENT OF GENETIC DIVERSITY IN SAFFLOWER

(*Carthamus tinctorius* L.) GERMPLASMS

PAVITHRA K. P, RAJESH S. PATIL, YALLAPPA HARIJAN, & NISHANTH, G. K

Department of Genetics and Plant Breeding, University of Agricultural Sciences, Dharwad, Karnataka, India

ABSTRACT

A quantum assessment of genetic divergence for fifteen quantitative characters among 150 accessions of safflower (*Carthamus tinctorius* L) representing different geographical areas by Mahalanobis D^2 statistical showed that there is a substantial genetic diversity. The D^2 values of accessions ranged between 10.90 to 84.32. The intra cluster distances were ranged from 18.94 to 30.87. These accessions were grouped into 24 clusters the clustering pattern necessarily associated with geographical diversity in the set of germplasm. Among the plant attributes biological yield, harvest index, plant height, volume weight, number of seeds per capitulum and capitula per plant were found to be important in the present study.

KEYWORDS: Safflower, D^2 Analysis, Genetic Divergence, Adaptation, Germplasm

INTRODUCTION

Safflower (*Carthamus tinctorius* L.) is one of oldest oilseed crop belongs to the family Asteraceae. It has multipurpose crop being grown over 60 countries in the world. India is the largest producer of safflower with 54 % area and 40 % production in the world. In India, It is cultivated in an area of 1.5 lakh ha with a production of 1.13 lakh tons giving a productivity of 726 kg/ha. Maharashtra and Karnataka are the first and second with reference to area and production, respectively whereas, productivity is highest in West Bengal (1000 kg/ha) followed by Bihar (805 kg/ha) and Karnataka (719 kg/ha) (Indiastat, 2014).

The assessment of the genetic diversity in crop species is of interest for the conservation of genetic resources, broadening of the genetic base and practical applications in breeding programs. Safflower possesses considerable diversity across different regions of the world (Knowles, 1989). In order to design an appropriate breeding program, it is important to know how much the phenotypic variation of a trait is heritable (Kearsey and Pooni, 1996), since the efficiency of a selection program is mainly dependent on the magnitude of genetic variation and heritability of a trait (Falconer and Mackay, 1996). Genetic diversity of a crop species has been investigated using either agro-morphological traits or molecular markers.

Genetic diversity is of considerable practical interest in any crop improvement programme. Precise information on the nature and degree of genetic divergence would help the plant breeder in choosing the right type of parents for different breeding programmes. Therefore, the present investigation was undertaken to study the nature and magnitude of genetic divergence in 150 germplasm accessions of safflower.

MATERIALS AND METHODS

Hundred and fifty germplasm accessions obtained from different parts of India and seven checks of safflower (*Carthamus tinctorius* L.) were selected for study. These accessions and checks were sown in the experimental area of Agriculture Research Station, Annigeri, Karnataka, India during *rabi* season 2011-2012, with spacing between rows was 45 cm and the distance between plants was 20 cm. Data were analyzed using Windostat software version 9.1. A recommended package of practice was followed to raise healthy crop under natural conditions.

Observations on yield and yield related traits viz., plant height (cm), rosette period (days), days to 50 % flowering, days to maturity, capitula per plant, capitulum diameter (cm), number of seeds per capitulum, floret weight (g), test weight (g), volume weight (g), oil content (%), hull content (%), biological yield (g), harvest index (%), seed yield per plant (g). The observations were recorded on five randomly selected plants for each accession. The genetic divergence was worked out by using Mahalanobis D^2 statistics as described by Rao (1952). On the basis of D^2 values the genotypes were grouped into different clusters by employing Tocher's method as outlined by Rao (1952).

RESULTS AND DISCUSSIONS

Group Constellations

A method suggested by Tocher (Rao, 1952) was used to group the accessions into different clusters based on D^2 values. The set of 150 accessions grouped into twenty four clusters indicating the presence of appreciable amount of genetic diversity among the accessions under study. The distribution pattern into various clusters is depicted in Table 1 & Fig.1. The maximum number of accessions (99) was grouped into Cluster I, followed by Cluster III with 17 accessions, Cluster VIII with 12 accessions and Cluster XVI with two accessions. Remaining twenty Clusters (II, IV, V, VI, VII, IX, X, XI, XII, XIII, XIV, XV, XVII, XVIII, XIX, XX, XXI, XXII, XXIII, XXIV) were solitary containing one accession each. The intra-cluster D^2 values ranged from 18.94 to 30.87 (Table 2). The average intra-cluster distance among the members of Cluster VIII was the maximum followed by among members of Cluster XVI. The inter-cluster D^2 values ranged widely with minimum value of 10.90 and maximum value of 84.32. Clusters XIII and XXII were strikingly diverse from the rest of the clusters. The divergence between these two clusters was high as evident from their high inter-cluster distance. The minimum inter-cluster D^2 value (10.90) was observed between Clusters IV and V, indicating a closer relationship between accessions of these two clusters. Selection of parents for hybridization from different clusters was performed on the basis of mean statistical distance as suggested by Bhat (1970).

Contribution of Characters towards Divergence

Among the fifteen characters studied, the most important character contributing to the divergence was biological yield, followed by harvest index, plant height, volume weight, number of seeds per capitulum, capitula per plant, hull percentage and rosette period (Table 3). These observations were in accordance with earlier studies by Shivani *et al.* (2011) and Safavi *et al.* (2012). The above results implied that in order to select genetically diverse genotypes for hybridization the material should be screened for important traits like biological yield, harvest index, plant height, volume weight, number of seeds per capitulum and capitula per plant. It is then expected that desirable segregants can be isolated from planned crosses between diverse accessions for the above traits. Farthest and nearest clusters have been grouped based on the D^2 value (Table 4). Indicating that genetic divergence between the groups based on divergence value helps for predicting the future hybrid development programmes.

Analysis of Cluster means

It indicated substantial variation among clusters grouped according to D² analysis (Table 5). Based on the range of means it is possible to know the characters influencing divergence. In the accessions of the present study, Cluster XV recorded the first rank for the yield contributing traits viz., plant height, capitulum diameter, number of seeds per capitulum and test weight. It indicates that combination of these traits is very important for the improvement of seed yield so accessions belonging to these clusters can be further used in genetic improvement. Similar results were reported by Ghongade and Navale (1995). Days to 50% flowering recorded the lowest mean in the Cluster VI. Rosette period was the shortest in the Clusters VI and XXII. Cluster XV had the highest mean value for capitulum diameter and number of seeds per capitulum. Oil content and volume weight were highest in Cluster IX. Biological yield and seed yield showed the highest values in Cluster XIII. The clusters with multiple accessions also had comparably higher values indicating the wide range of variability available in the germplasm collection. Such distribution has also been reported by Pourdad and Singh (2002) and Shivani *et al.* (2011). The well spread out accessions can be utilised in genetic improvement programmes. Cluster XV had highest plant height and low plant height was observed in the Clusters VI, XVIII, XVII and XXII while remaining clusters had moderate plant height indicating the wide range of genetic diversity available in the accessions.

PH: Plant height (cm) RP: Rosette period (days) DFP: Days to fifty percent flowering DM: Days to maturity

CPP: Capitula per plant CD: Capitulum diameter (cm) NSPC: Number of seeds per capitulum FW: Floret weight

(g)

TW: Test weight (g) VW: Volume weight (g) OC: oil content (%) HP: Hull percentage

BY: Biological yield per plant (g) HI: Harvest index (%) SYPP: Seed yield per plant (g)

Figure 1: Dendrogram Showing Clustering of 150 Safflower Accessions by Tocher's Method
